# Occupational Exposure to Pesticides And Neurobehavioral Outcomes: Impact Of Different Exposure Measures on the Association

Asst. Prof. Samuel Fuhrmann  
Head Research Group: Agricultural Health  
Swiss Tropical and Public Health Institute

Symposium O4A3, 16.3.2023

# Conflict of interest and funding

No conflict of interest

Funding:

Part of the IMPRESS Study funded by Croplife Europe

([www.impress-project.org](http://www.impress-project.org))

Firewall between funder and researchers via independent Scientific Advisor Board

Mumbai India

# Content

1. PESTROP Study with smallholder farmers in Uganda
2. Different measures on how to assess self-reported pesticide exposure
3. Observed exposure-health associations

# PESTROP

## Pesticide use in Tropical settings

# Study design

- **Longitudinal study of 253 smallholder farmers (2017 and 2019)**
- **Conventional and organic smallholder farmers**
  - Farm size less than 20 ha
  - Subsistence farmers
  - Sell in the local and regional markets;
  - Grow: beans, maize, sweet potatoes, banana, cassava, coffee, tomatoes, and groundnuts

- Study protocol: Fuhrmann S, *et al.* *JMIR Res Protoc* 2019
- KAP of pesticide handling: Staudacher et al. 2020 *Environmental Health Insights*
- Pesticides in air: Fuhrmann et al. 2020 *Chemosphere*
- Information seeking behavior: Diemer et al. 2020 *Journal of Cleaner Production*
- Etc.

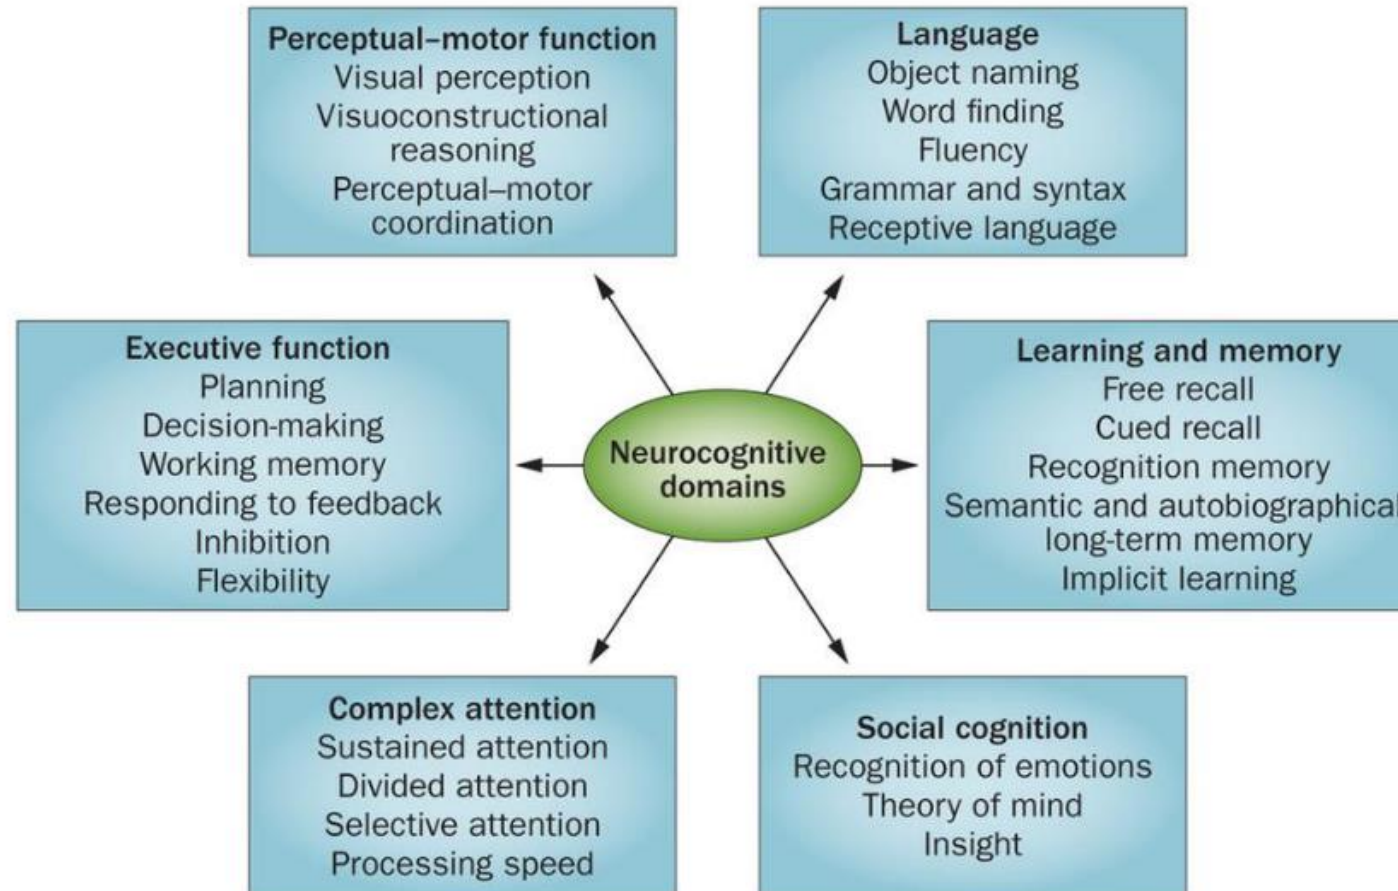

**EPICOH 2023**

Mumbai India

# 11 Neurobehavioral tests covering five neurocognitive domains

- Language, memory, attention, executive function, and motor function

# Cognitive function impaired due to glyphosate exposure

Environment International 152 (2021) 106477

## Exposure to multiple pesticides and neurobehavioral outcomes among smallholder farmers in Uganda

Samuel Fuhrmann<sup>a,\*</sup>, Andrea Farnham<sup>b,c</sup>, Philipp Staudacher<sup>d,e</sup>, Aggrey Atuhaire<sup>f</sup>, Tiziana Manfioletti<sup>b,c</sup>, Charles B. Niwagaba<sup>g</sup>, Sarah Namirembe<sup>f</sup>, Jonathan Mugweri<sup>f</sup>, Mirko S. Winkler<sup>b,c</sup>, Lutzen Portengen<sup>a</sup>, Hans Kromhout<sup>a</sup>, Ana M. Mora<sup>h,i</sup>

Neurobehavioral outcome	MIP
BVRT (scores)	0.18
Finger tapping dominant hand (scores)	0.29
Trail making A log10 (minutes)	0.31
Finger tapping non-dominant hand (scores)	0.42
Digit symbol (scores)	0.45
Semantic verbal fluency (scores)	0.50

**Zoom Webinar**

„Pesticides mixtures“

28 April 2022

3 pm – 5 pm (CEST)

Registration required

**AGRICOH**

Assessing the effect of pesticide biomarker mixtures on neurobehavioral outcomes among smallholder farmers in Uganda

**EPICOH 2023**

Mumbai India

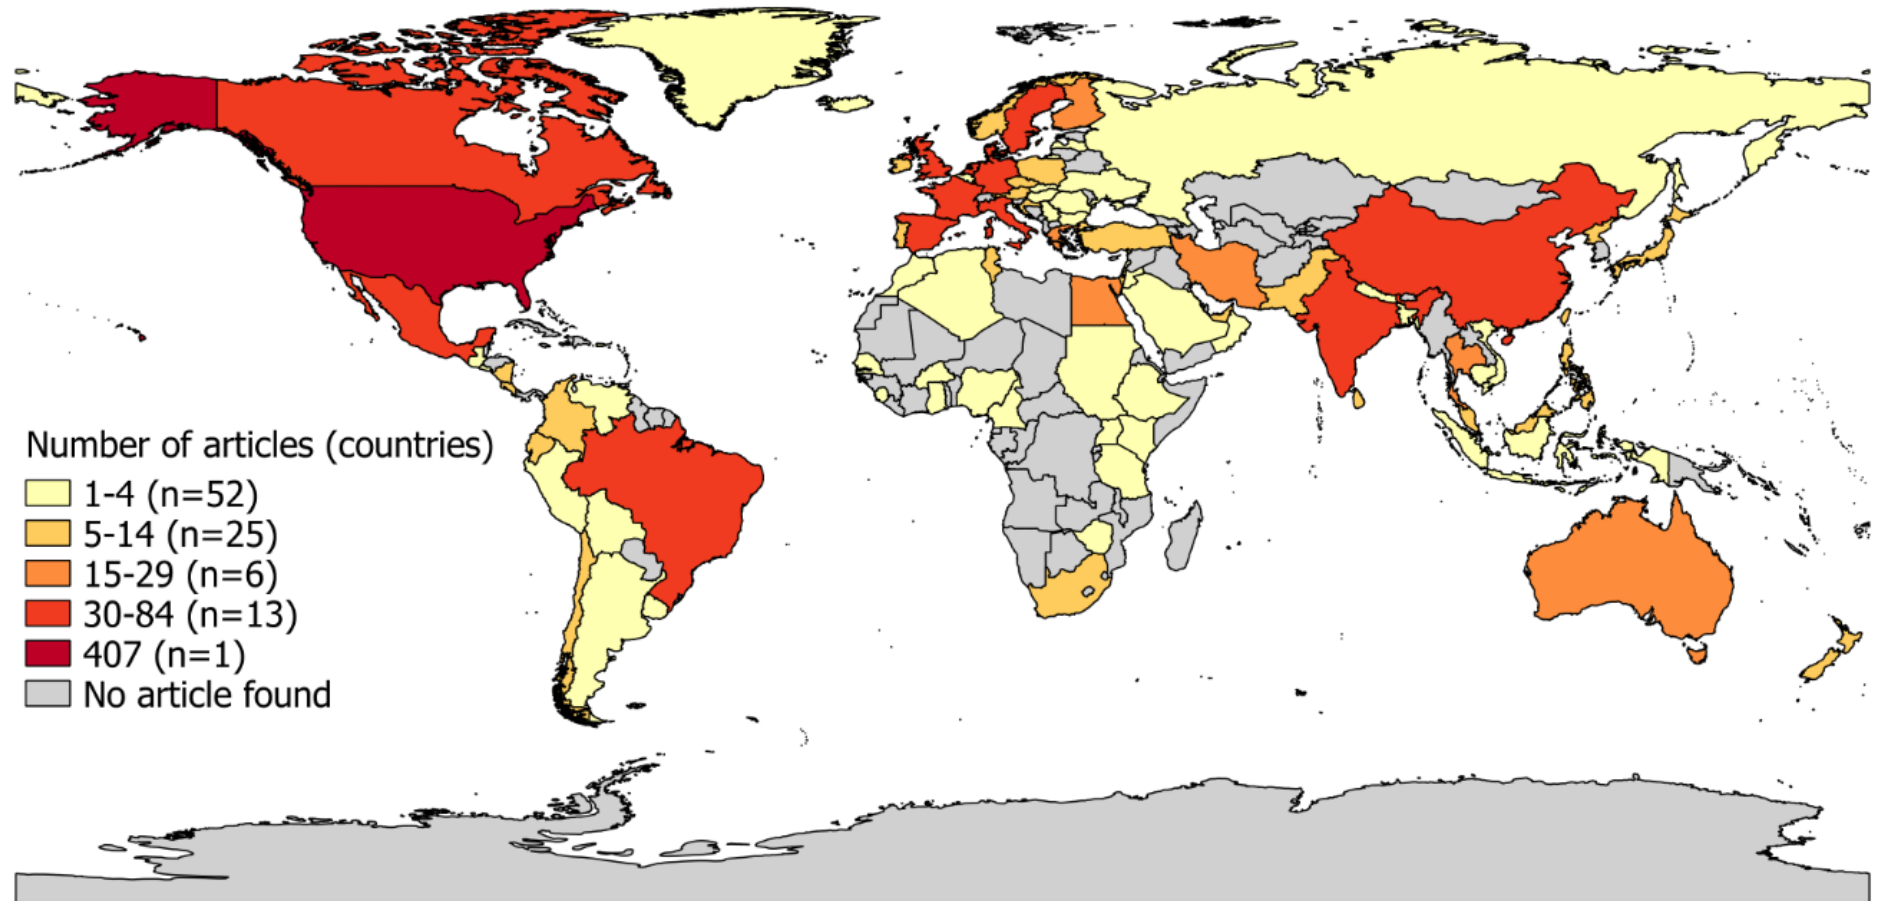

There are different ways to assess pesticide exposure...

How can an exposure contrast be established in a smallholder farming population in Uganda?

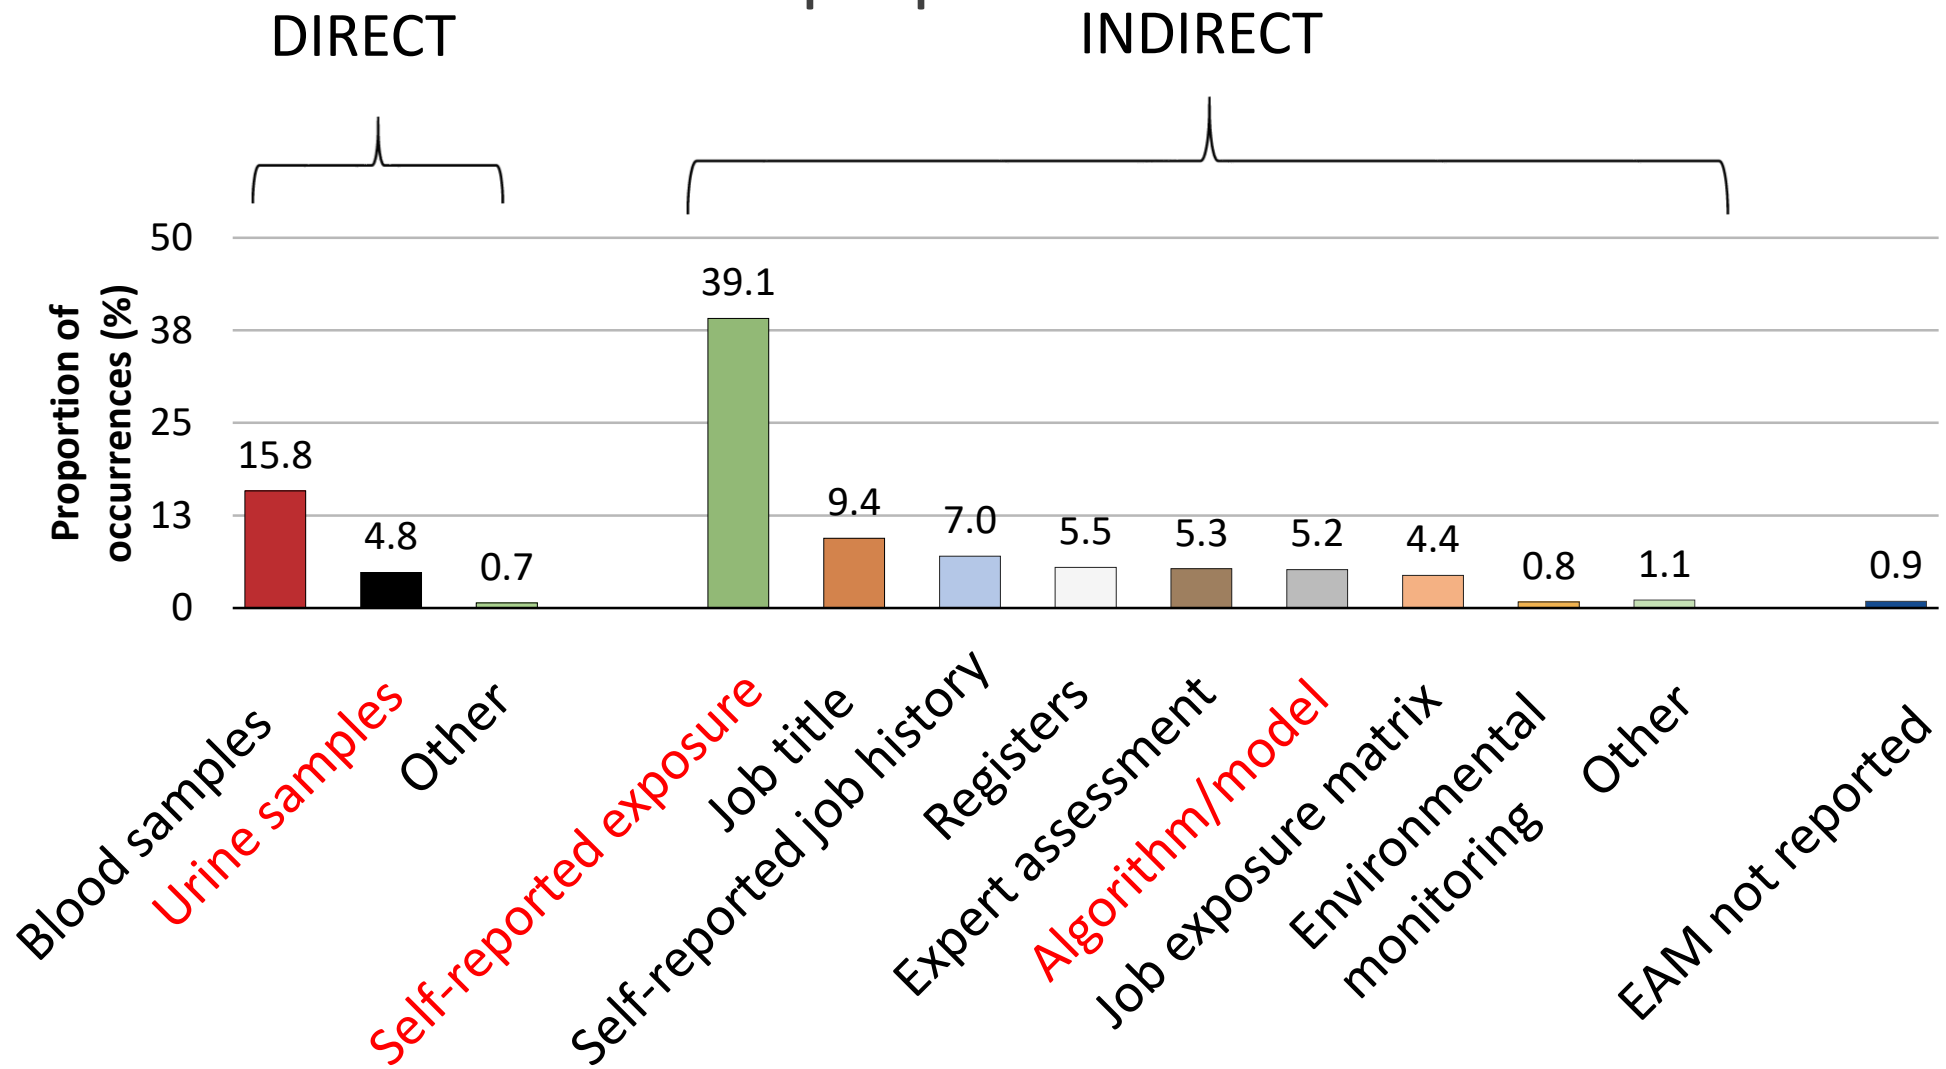

# Literature review on pesticide exposure assessments in occupational epidemiological studies

(Ohlander et al. 2020)

# Proportion of exposure assessment methods reported in the 1'298 papers

(Ohlander et al. 2020)

# Uganda smallholder spray in median 9 days per year (IQR 26)

→ Glyphosate and Mancozeb chosen

# Exposure intensity scores (EIS)

- **Exposure-intensity score (EIS) for an average application =**

(mixing + application)

x frequency of PPE use

x change of cloths

x shower after application

	Mixing	Spray	PPE Change	Shower	Total EIS
Min	5	8	0.14	0.7	0.89
Max	5	8	1	1	13

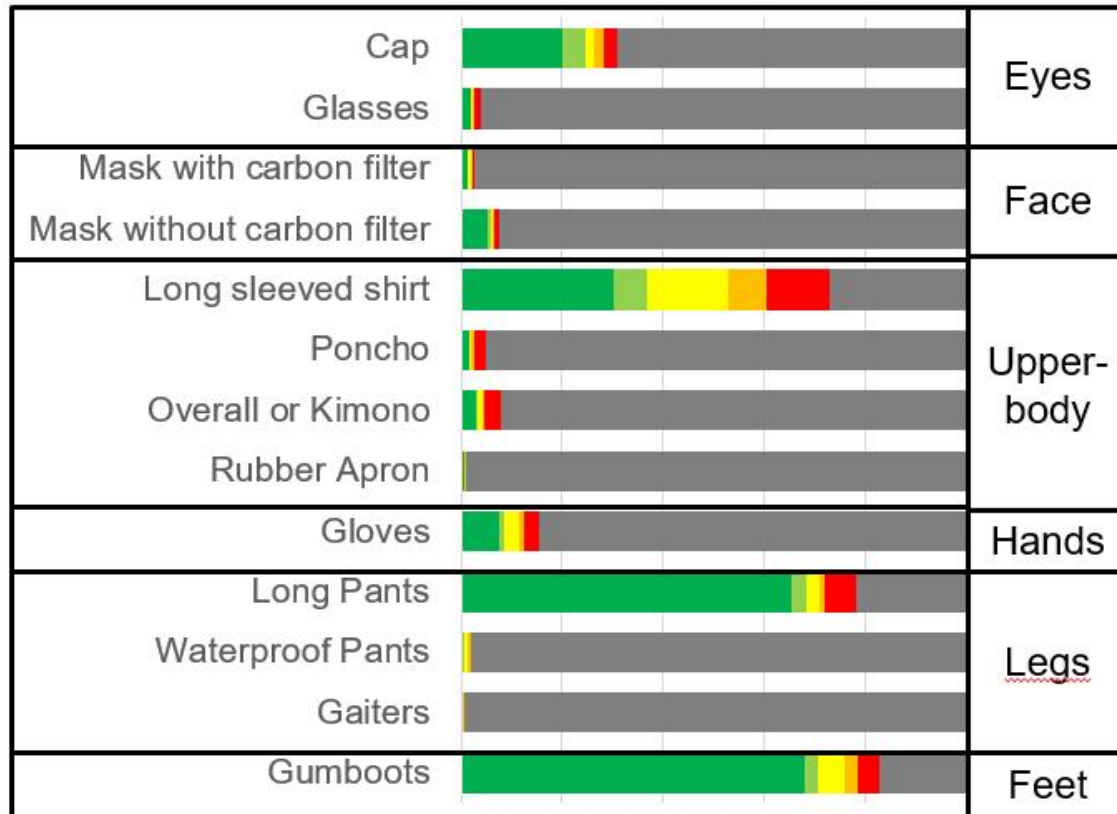

- **Cumulative yearly EIS**

**Year EIS** = Exposure-intensity score x total yearly application days

Variability and predictors of weekly pesticide exposure in applicators from organic, sustainable and conventional smallholder farms in Costa Rica

Samuel Fuhrmann <sup>1</sup>, Philipp Staudacher <sup>2,3,4,5</sup>, Christian Lindh <sup>6</sup>,  
Berna van Wendel de Joode <sup>7</sup>, Ana M Mora <sup>7,8</sup>, Mirko S Winkler <sup>4,5</sup>,  
Hans Kromhout <sup>1</sup>

# Exposure intensity scores (EIS)

0% 20% 40% 60% 80% 100%

■ Always      ■ Often      ■ Sometimes  
■ Rarely      ■ No Use      ■ No Access

# Exposure measures used to characterize glyphosate and mancozeb exposure

Original exposure measures based on information collected in 2017 indicating exposure for the previous year:

1. Application status (yes/no)
2. Number of application days
3. Average exposure-intensity scores of an application (EIS) derived from a semi-quantitative exposure algorithm and
4. Number of EIS-weighted application days.

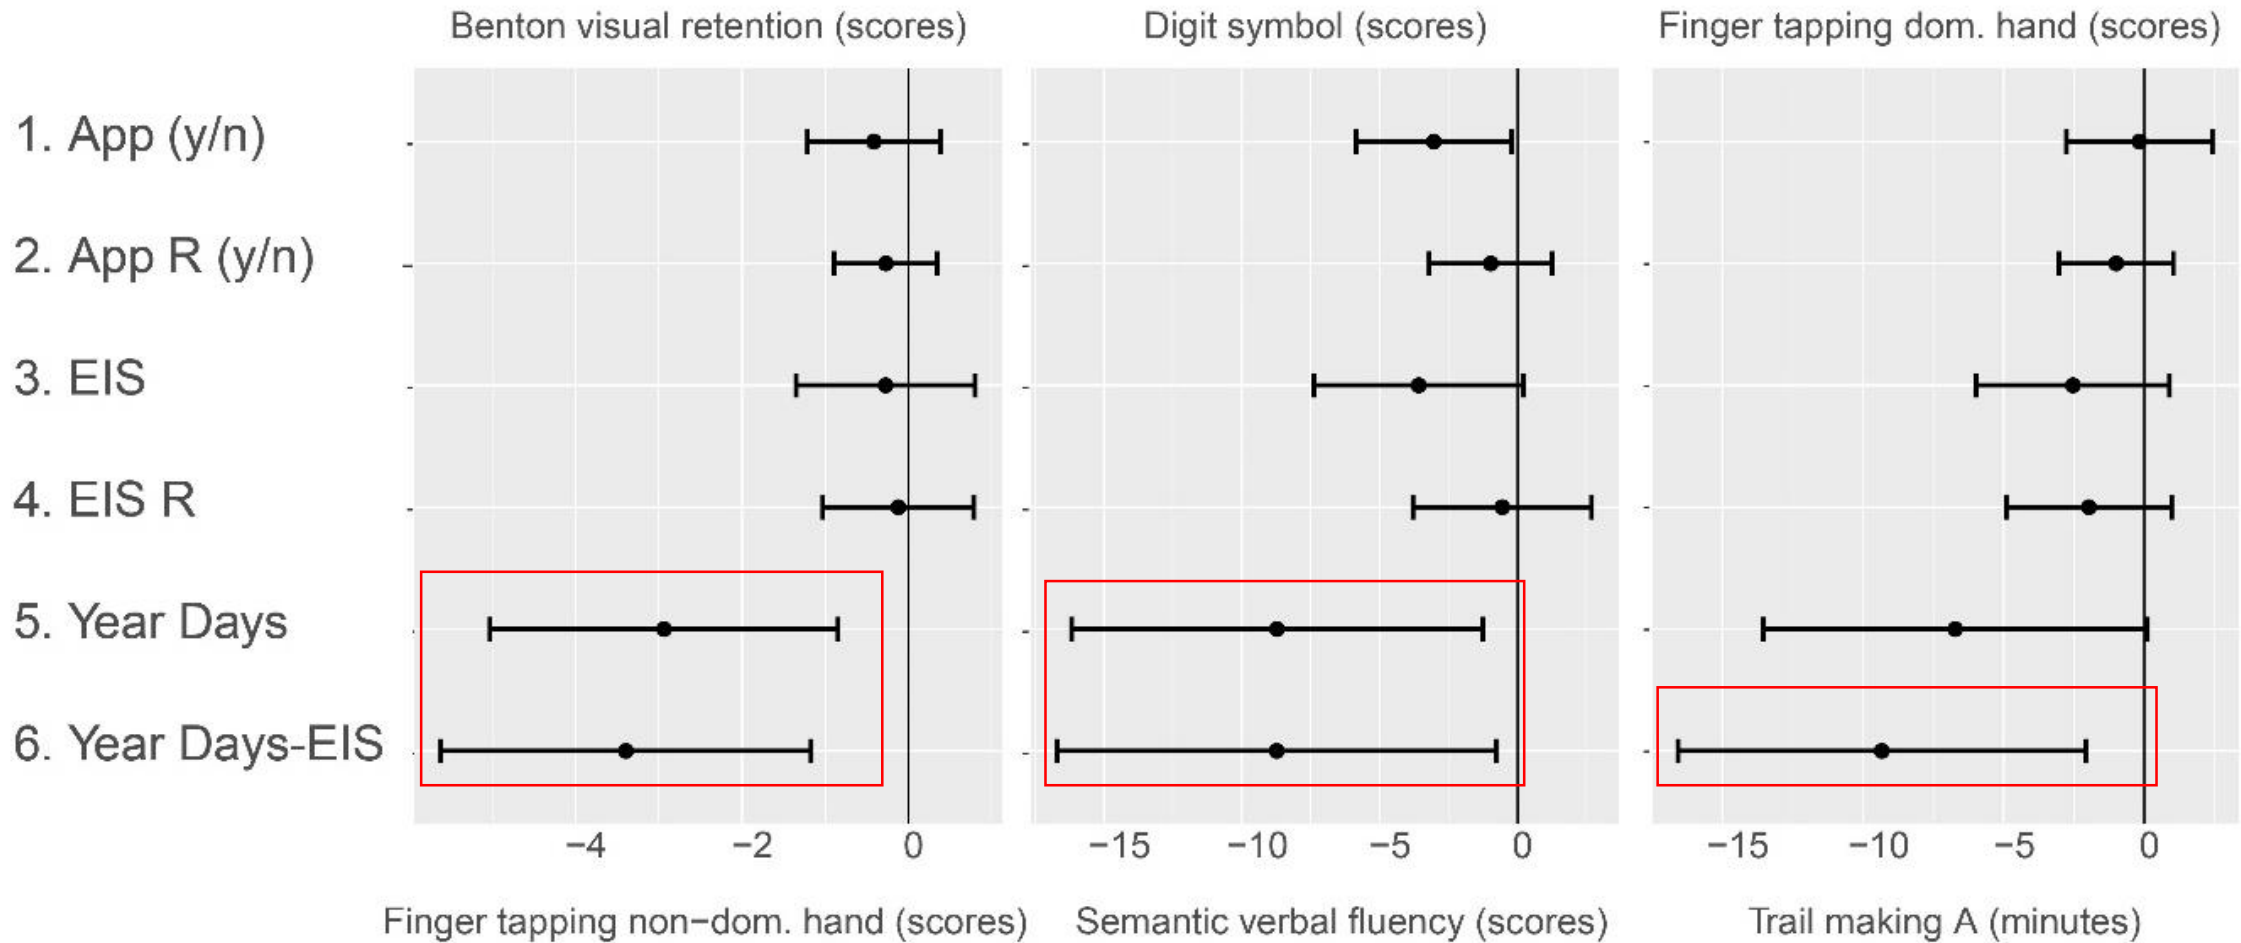

Recalled information collected in 2019 resulted in two additional measures:

1. Re-called application status and
2. Re-called EIS.

# Associations for glyphosate application days per year and EIS adjusted application days with different neurobehavioral outcomes

## Neurobehavioral outcomes

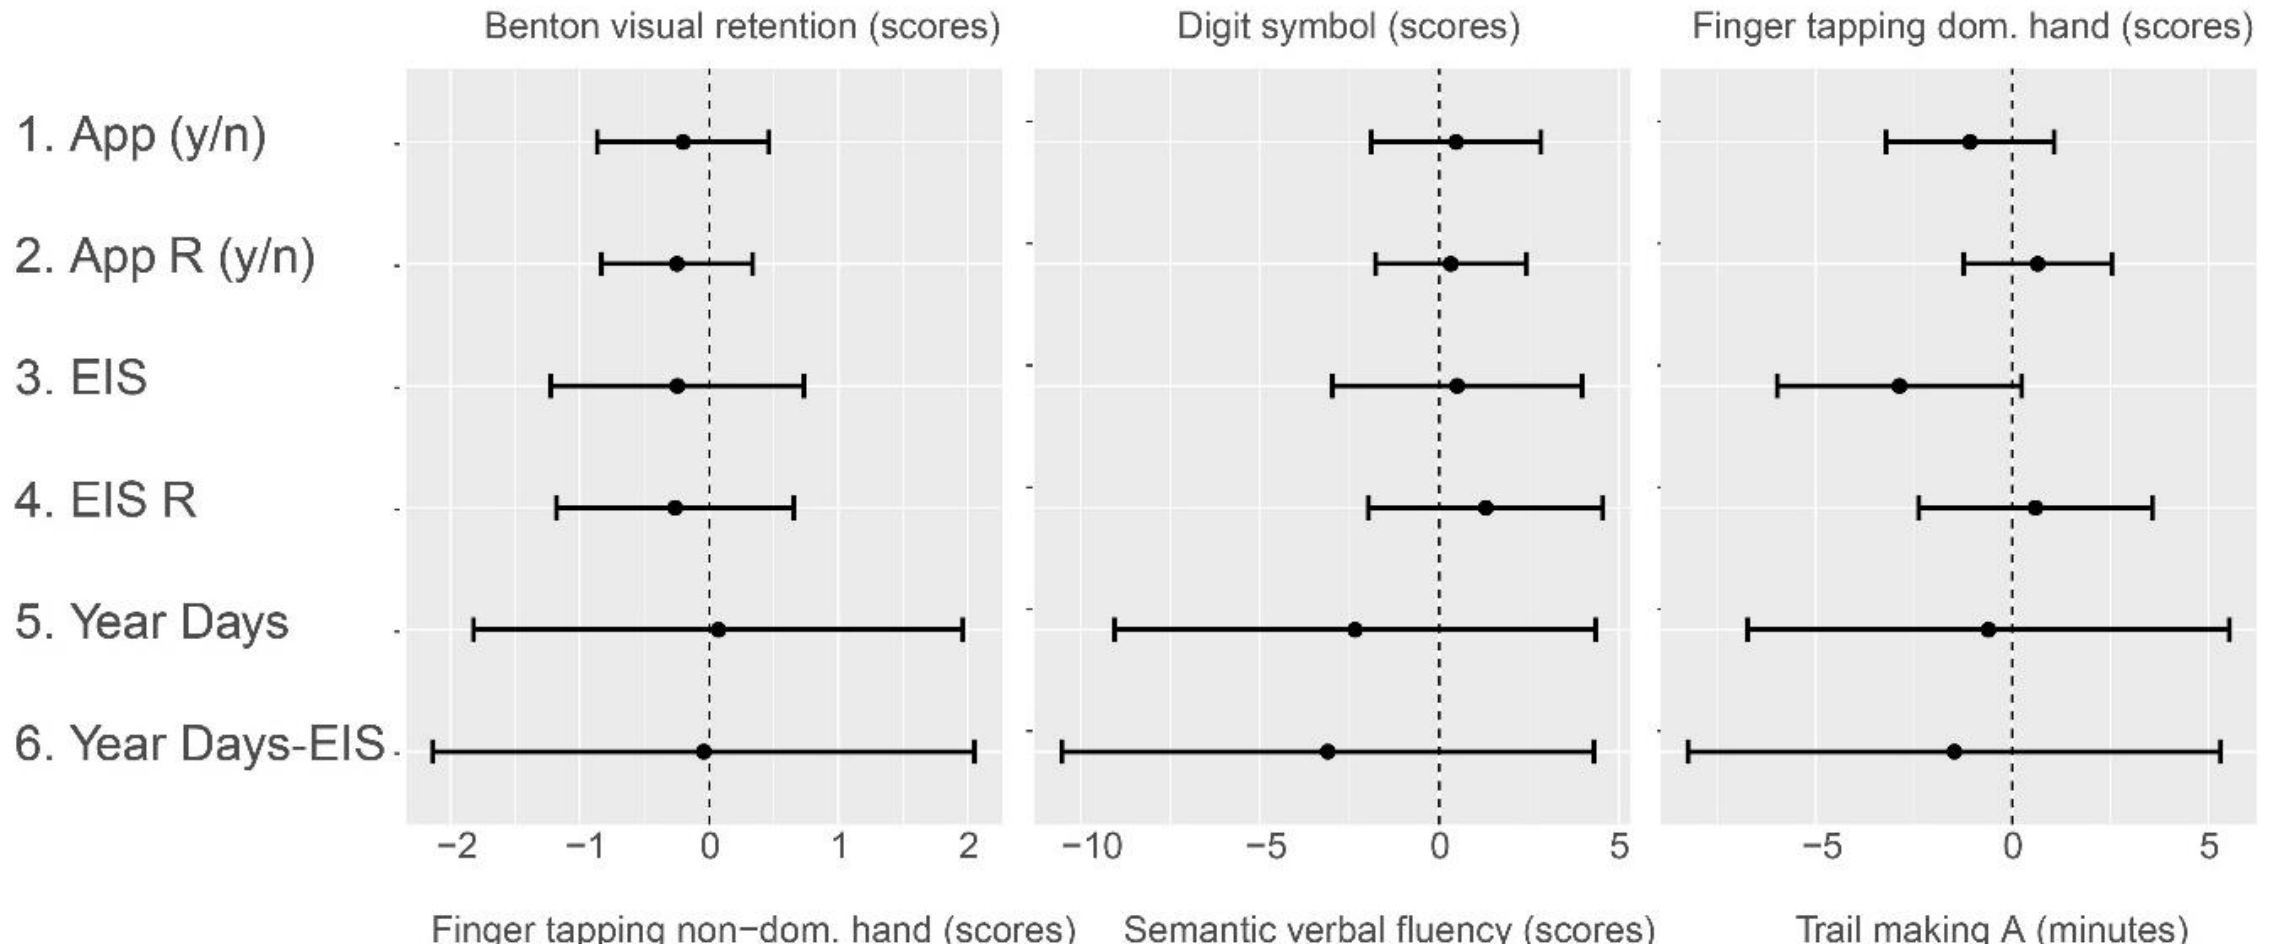

Multiple regression analysis adjusted for confounders (sex, age, education, alcohol, head injuries, HIV)

Continuous exposure assessment measures (#3-6) were normalized on a scale between 0 and 1  $(x - \min(x)) / (\max(x) - \min(x))$  before the analysis. App = application (yes); R = Recall; EIS = exposure-intensity scores.

# Null findings for mancozeb exposure measures

## Neurobehavioral outcomes

**Multiple regression analysis adjusted for confounders (sex, age, education, alcohol, head injuries, HIV)**

Continuous exposure assessment measures (#3-6) were normalized on a scale between 0 and 1  $(x - \min(x)) / (\max(x) - \min(x))$  before the analysis. App = application (yes); R = Recall; EIS = exposure-intensity scores.

# Three take home messages

1. The relation between different self-reported glyphosate exposure measures and neurobehavioral test scores appeared to be robust.
2. When based on recalled exposure measures, positive associations were no longer present.
3. Future epidemiological studies on self-reported exposure should critically evaluate the potential bias towards the null in observed exposure-response associations.
